

Funnel attribution pathway

A journey view connecting traffic, events, devices, and channel decisions

PORTFOLIO DEMONSTRATION - ILLUSTRATIVE DATA

QUESTION

How should a reviewer interpret a funnel when one click can produce multiple conversion events?

DECISION

Show macro and micro events together, then treat rates above 100% as a governance question.

EVIDENCE RETAINED

Dashboard layout, channel comparison, event-stacking analysis, and the control framework.

VALIDATION

Audit event definitions, deduplicate purchase IDs, reconcile channels, and test mobile completion friction.

Figure 1. Apple Omni-Channel | Funnel Attribution & Micro-Conversion Pathway, portfolio demonstration dashboard in Google Looker Studio.
Reporting window: Jan 1, 2020 – Jul 24, 2024.

1 Macro Funnel Scorecards

2 Channel Volume

3 Device Attribution

4 Conversion Pathway Matrix

The report follows the funnel's own shape: macro status at the top, channel and device comparisons in the middle, and granular campaign-level detail at the bottom. The layout mirrors the journey it reports on, so reading top to bottom is reading the funnel top to bottom.

1 Macro Funnel Scorecards

Four scorecards anchor the top of the report: ToF Impressions, Mid-Funnel Clicks, BoF Conversions, and Macro Conversion Rate. Placing all three funnel stages side by side lets a stakeholder spot the steepest ratio drop at a glance, in this account, the impressions-to-clicks stage, rather than assuming the click-to-conversion stage is always where the largest loss occurs.

2 Channel Volume: Clicks vs. Conversions

A grouped bar chart plots Mid-Funnel Clicks against Conversions for every channel: Performance Max, Search, Display, Shopping, and Video. Pairing the two metrics side by side, rather than showing each in a separate chart, makes it immediately visible which channels convert more efficiently than they acquire, and which generate clicks without a proportional conversion return.

3 Device Attribution Breakdown

A donut chart decomposes bottom-of-funnel conversions by device: mobile, computers, tablets, and TV screens. Because it is scoped to completed conversions rather than sessions or clicks, it answers a more specific question than a typical device chart: not where the audience starts, but where the audience actually finishes.

4 Conversion Pathway & Micro-Tracking Matrix

A granular table breaks down Impressions, Clicks, Conversions, and Conversion Rate by individual campaign. This is the dashboard's diagnostic layer: it is where conversion rates exceeding 100% become visible and attributable to specific campaigns, turning what could look like a data anomaly at the summary level into a traceable, campaign-level signal.

DEMO INTERACTIVE REPORT

4 Key Insights & Data Analysis

4.1 Channel Efficiency: Performance Max vs. Search and Display

Performance Max generated **304.9K** clicks against **593.6K** conversions, meaning it produced nearly double the conversions relative to clicks, a ratio only possible under a multi-touch conversion model where a single click session generates multiple counted conversion events downstream. Search converted **241.9K** clicks into **142.5K** conversions, and Display converted **152.7K** clicks into a comparatively low **93.3K**. Shopping registered minimal volume and Video recorded none in this window.

STRATEGIC READ

PMax is not marginally ahead of Search and Display, it is operating in a different efficiency band entirely, converting at nearly double its click volume. Channel-level budget models should treat this ratio as a structural signal, not a seasonal fluctuation.

BUSINESS IMPACT

Because PMax converts more efficiently than it acquires clicks, incremental funnel budget should route to PMax ahead of Search or Display expansion, since the same click volume returns a materially larger downstream conversion outcome.

4.2 Device Behavior: Mobile Conversion Dominance

70.6% of bottom-of-funnel conversions are attributed to mobile devices, with Computers at **18.1%** and Tablets at **11.3%**; TV screens registered negligible share. This confirms the funnel's completion stage, not only its browsing stage, is overwhelmingly mobile.

STRATEGIC READ

Mobile is not only where the audience starts, it is where the audience finishes. Any funnel-stage friction audit, landing page speed, checkout flow, form length, should prioritize mobile first, since that is where most of the funnel's value is actually realized.

BUSINESS IMPACT

This justifies auditing mobile completion flows, not just mobile entry pages, as the highest-leverage conversion lever available: three in four bottom-funnel conversions depend on a frictionless mobile finish, not merely a mobile click.

4.3 Micro-Conversion Anomalies: Conversion Rates Exceeding 100%

The pathway matrix surfaces multiple campaigns posting conversion rates above 100%, led by the top PMax campaign at **129.8%** (197.8K conversions on 95.9K clicks), with a second PMax structure reaching **192.46%**. These are not data errors; they reflect a micro-conversion event model in which a single click session can trigger multiple counted conversion events (add-to-cart, checkout start, purchase, and post-purchase engagement each logged individually against one click).

CAMPAIGN SIGNAL	OBSERVATION	STRATEGIC IMPLICATION
Top PMax conversion rate	129.8% (197.8K conversions on 95.9K clicks)	Strong multi-touch engagement, expansion candidate
Second PMax structure	192.46% conversion rate	Highest event-density signal in the account
Display conversion rate	61.13%, below the account average	Likely mobile-completion friction, not a reach problem

STRATEGIC READ

A conversion rate above 100% should be read as an event-density signal, not a literal per-click success rate. The campaigns posting the highest over-100% rates are the ones generating the most micro-conversion touchpoints per session, an indicator of strong on-site engagement depth, not a measurement error.

BUSINESS IMPACT

Because these campaigns already demonstrate high multi-touch engagement, they are strong candidates for creative and audience expansion: the platform is proving it can extract multiple value events from the same click, and scaling spend should compound that efficiency rather than dilute it.

FORWARD OUTLOOK

If Performance Max's conversion-to-click ratio holds as spend scales, incremental budget concentrated in PMax should continue returning a disproportionate share of bottom-funnel conversions relative to clicks. This should be validated against impression share saturation as PMax spend increases, since the ratio may compress once the channel exhausts its most efficient inventory.

Risk & Watch Items

The following signals should be tracked alongside the core funnel scorecards so pathway risk is caught before it distorts budget decisions.

RISK	MONITORING METRIC
------	-------------------

Micro-conversion double counting	Conversion event definition audit, quarterly
Mobile completion friction	Mobile funnel drop-off, click to conversion
PMax conversion concentration	Conversion share, top 3 campaigns
Search and Display click waste	Click-to-conversion ratio, non-PMax channels
Video and Shopping channel dormancy	Impression and click volume, monthly

5 Strategic Recommendations

The findings above translate into three actionable budget-reallocation steps, each addressing a distinct point in the funnel rather than a single campaign-level fix.

1. Reallocate Budget Toward Performance Max

Given PMax's higher-than-1.0 conversion-to-click ratio and its two campaigns already exceeding 129.8% and 192.46% conversion rates, incremental budget should shift from Display, currently returning 93.3K conversions on 152.7K clicks, toward these proven PMax structures, prioritizing the highest-conversion-rate campaigns as the primary scaling targets.

2. Rebuild Display and Video Around Mobile Completion, Not Just Mobile Reach

With 70.6% of bottom-funnel conversions completing on mobile, Display and Video assets, the latter currently registering zero clicks and conversions, should be redesigned around mobile-first creative and landing experiences before any budget increase. Acquiring clicks without a mobile-optimized completion path is the likely driver of Display's comparatively weak 61.13% conversion rate.

3. Formalize Micro-Conversion Event Governance

Because several campaigns exceed 100% conversion rate, the underlying calculated metric should be documented and standardized across the account, detailed in Section 6, so budget conversations reference a consistent, audited definition of what counts as a conversion event, preventing the metric from being misread as an error rather than an efficiency signal.

6 Tech Stack & Data Modeling

The dashboard is built entirely on Google's native BI stack. Looker Studio serves as the visualization and governance layer, while the Google Ads data connector provides a live, connector-driven pipeline for impressions,
